

Assignment 2: Tables, Forms, and Scoped Application

Objective:

Design and configure a scoped application named **'TechNova Project Management'** to manage internal projects, resource allocations, and employee skills tracking in ServiceNow.

Requirements:

Requirement 1: Project Management

We need a way to track our internal projects. For each project, we need to know its name, who's managing it, the current status (like Planning, In Progress, Completed, or On Hold), how many developers, QAs, and architects are needed, when we expect it to finish, when it actually finished, and its priority (High, Medium, Low). We also need a space to describe the project. Each project should have a unique ID and project logo field. Add a Skills field that references the Skills table that shows list of required skill for current project. This field should be of type list, allowing users to select multiple skills.

Requirement 2: Resource Allocation

We need to assign specific people to work on these projects and need to specify the assigned role (Architect, QA, Developer), which group they belong to and who is actually assigned and the current status of the assignment (like Approval Requested, Approved, or Rejected). We also need to track on what particular date someone was assigned, who requested assignment and any comments about the assignment, and which project it's for. Each assignment should have a unique ID.

Requirement 3: Skill Tracking

We need to keep track of the different skills our employees can have. For each skill, we need a name, a category (like Technical, Management, QA, DevOps), and a description.

Requirement 4: Connecting People and Skills

We need to link our employees to the skills they possess and indicate their proficiency level (Beginner, Intermediate, Expert) for each skill.

Requirement 5: Visibility between Projects and Assignments

When looking at a project, we should easily see all the people assigned to it. Similarly, when looking at a skill, we should see all the people who have that skill. Also, when looking at a user, we should see all their skills and their assignments.

Requirement 6: Project Issue

This table should be created by extending the **Task** table so it inherits core workflow capabilities like the **Status** field and supports SLA tracking. The status should include choices such as **New, In Progress, On Hold, Resolved, and Closed**. The table must also capture fields such as **Issue Title, Issue Description, Project, Assigned To, Assignment Group, Resolution Notes, Priority** (High, Medium, Low), and **Severity** (Critical, Major, Minor). With this structure in place, TechNova can properly log issues, track ownership, and measure response and resolution performance through SLAs.

Requirement 7: Navigation

We need a clear and organized menu within the application to access: A list of all projects and a way to create new ones (only Operations should be able to create new projects). A list of all resource assignments. A list of all skills and a way to create new ones (only Operations should be able to create new skills). A list of all resource skill mappings and a way to create new ones (only Operations should be able to create new skill mappings).

Requirement 8: Role-Based Reference Qualifier

Add a reference qualifier on all user reference fields (e.g., *Project Manager*) so that only users with the **Manager** role (or members of the **Manager** group) are visible and selectable.

Notes:

This assignment should be implemented within a scoped application named 'TechNova Project Management'. Ensure relationships between tables are properly defined using reference fields and related lists. Use meaningful field names, labels, and appropriate data types (choice, reference, string, date, etc.).
